Abstract

A High-frequency Acoustic Recording Package (HARP; Wiggins and Hildebrand 2007) was deployed between April and September 2009 in Jacksonville, FL, at Site B in 37 m. This HARP sampled at 200 kHz for 5 minutes of every 15 minutes and recorded for 157 days between 2 April 2009 and 5 September 2009. Long-Term Spectral Averages (LTSAs) were created for three frequency bands (10 Hz – 1000 Hz, 500 Hz – 10 kHz, and 1 kHz – 100 kHz) and scanned for marine mammal vocalizations and mid-frequency active sonar. Vocalizations of sperm whales and unidentified delphinids were detected in the data.
Methods

The April – September 2009 Jacksonville Site B HARP (JAX 01B) was deployed at 30.2582° N, 80.4282° W on 30 March 2009 (recording started on 2 April 2009) and recovered on 16 September 2009 (recording ended on 5 September 2009). The instrument location is shown in Figure 1. Bottom depth at the deployment site was approximately 37 m. A schematic diagram of the JAX 01B HARP is shown in Figure 2.

Figure 1. Location of HARP deployment sites in the Jacksonville survey area. The location of the Jacksonville 01B HARP is shown in green.
Figure 2. Schematic diagram showing details of the JAX 01B HARP. Note that diagram is not drawn to scale.

Data were acquired at a 200 kHz sampling rate for 5 minutes every 15 minutes during the JAX 01B deployment. This deployment provided a total of approximately 1255 hours of data over the 157 days of recording. The data collected were manually scanned for marine mammal vocalizations using Triton (Hildebrand Lab at Scripps Institution of Oceanography, La Jolla, CA). The effective frequency range of the HARP (10 Hz – 100 kHz) was divided into three
parts for this manual review: 10-1000 Hz, 500 Hz – 5000 Hz, and 1-100 kHz. The resulting LTSAs had resolutions of 5 s in time and 1 Hz in frequency (for the data decimated by a factor of 100: 10-1000 Hz band), 5 s in time and 10 Hz in frequency (for the data decimated by a factor of 20: 0.5-10 kHz band), and 5 s in time and 100 Hz in frequency (for the data not decimated: 1-100 kHz). All data were analyzed by visually scanning the LTSAs in appropriate frequency bands. LTSAs that were decimated by a factor of 100 were inspected for sounds produced by minke whales only. These low-frequency data could not be effectively analyzed for marine mammal sounds due to high levels of ambient noise (in large part caused by instrument strumming and fluid flow at the hydrophone due to the shallow water environment). Such high levels of ambient noise decrease the detection ability for low-frequency sounds. Analysis for minke whale vocalizations was performed for a separate project looking at their seasonal presence, although no calls were detected in this dataset. The mid-frequency LTSAs (0.5-10 kHz) were inspected for mid-frequency active sonar. Non-decimated LTSAs (1-100 kHz) were inspected for odontocete whistles and clicks. The presence of vocalizations and mid-frequency active sonar was determined in one-minute bins, and vocalizations were assigned to species when possible.

Results

Table 1 summarizes the detected and identified marine mammal vocalizations for the JAX 01B HARP deployment. Figures 3-4 show the daily occurrence patterns for the different marine mammal groups (classified to species when possible). Figure 5 shows the occurrence of mid-frequency active sonar. Underwater ambient noise during this deployment is shown in Figure 6.
Detected odontocete vocalizations included clicks and whistles (Figures 3-4). Most of these detections were assigned to the unidentified odontocete category (Figure 3). Sperm whales were detected on only six days during daylight hours (Figure 4).
